Ground Water Conditions Idaho National Laboratory

Idaho Department of Environmental Quality

October 2012

INL Facilities

(Bartholomay, et al. USGS, SIR 2012-5169)

Ground Water Under the INL

Depths to ground water increase from about 200 ft at TAN to about 900 ft on southern boundary of INL in ESRPA

Perched aquifers occur where infiltrating water from the Big Lost River, leaking pipes, or unlined ditches or ponds accumulates on top of lower permeability strata such as interbeds, dense layers of basalt, or heat altered interbeds

Perched aquifers are hard to delineate, saturated pockets may be hydraulically isolated, water yield is low

ESRPA is highly productive and is designated as a Sole Source Aquifer by **U.S. Environmental Protection Agency**

Ground Water Flows in the Eastern Snake River Plain Aquifer

Ground water flow paths under INL eventually discharge near King Hill area

King Hill marks the western terminus of the Eastern Snake River Plain Aquifer (ESRPA)

Multi-Well Ground Water Elevation Changes

Three trends in water levels

A general decline of about 0.6 ft/yr

Small seasonal fluctuation typically less than 2 feet per year; rebounds in the spring, declines until next spring

Larger multi-year cycle may exceed 10 feet; dependent upon snowpack in recharge areas

Water Level Contour Map June 2007 WAG 10, Monitoring Report for FY 2011

Ground water flow is toward the southwest across the INL

Hydraulic gradient is flatter around INTEC and CFA indicating greater transmissivity in the ESRPA

Ground water velocities around TAN are estimated to be about 0.6 ft/day

Ground water velocities around INTEC are estimated to be 10 ft/day or higher

Monitoring wells shown are small fraction of total monitoring wells on the INL

Multiple Modeling Efforts

CERCLA

- TAN ground water fate & transport
- TRA ground water fate & transport
- INTEC ground water fate & transport & unsaturated zone reactive transport
- RWMC unsaturated and saturated zones fate & transport
- Site wide ground water fate & transport under WAG 10

DOE Performance Assessments

- Required by DOE orders 435.1
- Revisited for INTEC (Tank Farm) in 2003 and 2006 and adjacent ICDF in 2003
- RWMC performed in 1994, revised in 2000 and again in 2007/2008

New Insight Into Flow Paths (Fisher, et al, USGS, SIR 2012-5152)

Multi-layer model constructed by USGS

Particle track modeling used to predict ground water flow paths

Ground water flow path complexity appears to increase as scale changes

Base from U.S. Geological Survey digital data, 1:24,000 and 1:100,000 Albers Equal-Area Conic projection, standard parallels 42°50 N, 44°10'N; central meridian 113°00'W; North American Datum of 1927.

B. Particle pathlines with starting locations in model layer 1

EXPLANATION

Particle pathlines with starting locations in model layer 1—particles primarily traveling in model layer 1

- Particles traveling at velocities greater than or equal to 0 and less than or equal to 15 feet per day (ft/d)
- Particles traveling at velocities greater than 15 and less than or equal to 30 ft/d
- Particles traveling at velocities greater than 30 and less than or equal to 60 ft/d
- Particles traveling at velocities greater than 60 and less than or equal to 100 ft/d
- Particles traveling at velocities greater than 100 ft/d

Model area boundary

Hydrogeologic zones, model layers 1

- 1—Younger rocks consisting of densely fractured basait and interbedded sediment, with a sediment thickness of generally less than 11 percent
- 2—Younger rocks consisting of massive, less densely fractured basalt and Interbedded sediment, with a sediment thickness of generally less than 11 percent 2—Intermediate-age rocks consisting of slightly altered fractured basalt and
- sediment, with a sediment thickness of generally less than 11 percent 4—Intermediate-age rocks consisting of slightly altered fractured basait and
- sediment, with a sediment thickness of generally less than 11 percent 11—Younger rocks consisting of densely fractured basalt and interbedded sediment, with a sediment thickness of generally more than 11 percent
- 22—Younger rocks consisting of massive, less densely fractured basait and interbedded sediment, with a sediment thickness of generally more than 11 percent
- 23—Intermediate-age rocks consisting of slightly altered fractured basait and sediment, with a sediment thickness of generally more than 11 percent
- 44—Intermediate-age rocks consisting of slightly attered fractured basalt and interhedded sediment, with a sediment thickness of generally more than 11 percent 6—Silici rocks, including rhybite domes and andesite

Test Area North

Sewage sludge was injected into ESRPA with TCE, Cs-137, Sr-90, & Tritium

TSF-05 (injection well) was surged and bailed to remove sludge

In situ bioremediation implemented in Hot Spot with air stripping of TCE from ground water at down gradient end of Medial Zone

Ground water quality continues to be monitored

Recently began implementation of rebound phase (stopped addition of in situ bio-amendments whey and sodium lactate) to observe changes in concentrations of TCE

Plume Map

Test Area North

Hot Spot and Medial Zone Progress 1997 to 2011

1997

Well

Naval Reactor Facilities

Major sources of contamination to ESRPA were Industrial Waste Ditch and unlined ponds; chromium is a contaminant of concern

Minor ground water contamination in a perched aquifer and ESRPA

NRF drilled new up gradient monitoring well to eliminate problems with sedimentary interbed movement through well screen

Advanced Test Reactor Complex (formerly Test Reactor Area)

Major sources of contamination were Injection well and unlined ponds

Contamination in perched aquifer and ESRPA

Contaminants include tritium, chromium, Sr-90, C0-60, & diesel

Idaho Nuclear Technology & Engineering Center

Waste water was injected in ESRPA containing I-129, Tritium, Tc-99, Sr-90, and lesser isotopes

Plumes from injection well have been tracked, at low concentrations, beyond the southern INL boundary

Contaminants released from leaking pipelines and valves within Tank Farm; Sr-90 mobilized because of high concentrations of sodium in waste stream; Sr-90 resides in first perched aquifer; remediation strategy is to reduce sources of water to perched aquifer to allow decay of Sr-90

Ongoing monitoring generally shows decreasing concentrations of I-129, Tritium, Sr-90, & Tc-99

Ground Water Monitoring Wells Around INTEC

Wells sampled for CERCLA + former injection well

Arc of monitoring wells located between INTEC and CFA

Variable completion depths for monitoring wells requires care in considering concentrations

Sr-90 Concentrations in Ground Water by INTEC

Sr-90 concentrations in ground water from past use of injection well are declining over time

Drinking water standard for Sr-90 is 8 pCi/L

Sr-90 in Groundwater vs. Time

Idaho Nuclear Technology & Engineering Center

Central Facilities Area

Contaminants include nitrogen found in form of nitrate in ground water, mercury by waste water discharge pipeline and disposal pond

CFA Landfills suspicioned to be sources of various organic compounds found in ESRPA but not at concentrations of concern

Nitrate plume is moving down gradient from CFA; some wells continue to show concentrations at or exceeding MCL

Radioactive Waste Management Complex

Historically carbon tetrachloride has exceeded drinking water standard in ESRPA until recently; isotopes of concern include C-14, tritium, Tc-99, I-129, Pu, & U

Vapor extraction from unsaturated zone has been ongoing since January 1996; additional vapor extraction by negative pressure applied to ARP structures for operations; and sludges containing CCl₄ are being removed

As of September 27, 2012, 137,475 lbs. of CCl_4 have been removed; 237,892 lbs of total volatile organic compounds have been removed

Probable mechanism for conveyance of CCl_4 to ESRPA is "partitioning of vapor phase to aqueous phase" at top of water table

Army Reactor Area, Power Burst Facility, and Material and Fuels Complex (formerly Argonne West)

Ground water contamination not found except for diesel in 1 monitoring well

Monitoring data continues to support lack of contamination in ESRPA

Ground Water Sampling Locations for OU 10-08

Sampling focused near southern boundary of INL

Some wells have multi-depth completions allowing depth specific sampling

Tritium Concentrations in USGS 104 & USGS 106

Ground Water Sampling Locations by INL Oversight Program - DEQ

Overall Ground Water Plumes in the ESRPA

Summary

Trends generally show decreasing concentrations in ground water with time

- Ongoing remediation at TAN is reducing amount of TCE in aquifer
- Ongoing remedial strategy at INTEC is to reduce loss of water from piping and managing storm water to retain Sr-90 in perched aquifer allowing for decay
- Ongoing vapor extraction and sludge removal at RWMC
- Ground water monitoring continues across the INL
- Final CERCLA remedies are not in place at INTEC or RWMC
